

Rook Dispatch

Product One-Pager · Owner: Product Management, Dispatch · Current release 4.2

The product in one line

Dispatch gets the right responder to the right incident, faster than a human coordinator working from a whiteboard and a phone list.

The core flow

- An incident arrives in the agency's console, entered by a dispatcher or pushed from the agency's own intake system.
- Dispatch ranks every available responder against that incident and produces a routing priority order.
- A callout offer goes to the highest-ranked responder on their mobile device.
- The responder accepts or declines. If they decline, or the offer times out, it moves to the next responder in the order.
- Acceptance closes the loop: the responder is marked engaged and the incident is assigned.

Users

User	Surface	What they do here
Agency dispatcher	Web console	Enters incidents, watches coverage, overrides routing when needed.
Handler	Web console	Manages a responder's availability windows and capability tags.
Responder	Mobile	Receives callout offers, accepts or declines, sets availability.

How we measure it

- **Callout acceptance rate** — the headline metric. Share of callout offers accepted rather than declined or timed out. Reported weekly, per agency and in aggregate.
- **Time-to-accept** — median seconds from offer sent to offer accepted.
- **Coverage gap** — incidents where no available responder matched the required capability tags.

Cadence and platforms

- Web console for dispatchers and handlers; native mobile for responders.
- Monthly releases. Routing configuration ships as part of the release, not as a runtime setting an agency can adjust.
